1. Few usable public corpora
faces recorded under conditions a study can use
2. Designs converge on the same corpora
hand-held phone, small screen, target position as gaze label
3. New clinical data recorded
large display, oculomotor tasks; held in separate silos
4. Release blocked by privacy
face video = personal and health data (GDPR, HIPAA)
5. Standard exits fail
blur / mask: gaze geometry lost
HE / FL: no shared benchmark
controlled access: restricted
6. Corpus stays unreleased or restricted
the next group finds the same few corpora
The data-scarcity cycle
Possible break at step 5: de-identification that removes identity and keeps gaze.
This paper measures whether any current method does.
